# Overview

## 7.1 Point estimate

- unbiased estimator
- mean squared error
- 7.2 Methods of point estimation
  - method of moments
  - method of maximum likelihood.

## 7.3 Sufficient statistic

- 7.4 Information and Efficiency
  - Large sample properties of the maximum likelihood estimator

## Definition

A point estimate  $\hat{\theta}$  of a parameter  $\theta$  is a single number that can be regarded as a sensible value for  $\theta$ .

 $\begin{array}{ccc} \text{population parameter} \Longrightarrow & \textit{sample} & \Longrightarrow \textit{estimate} \\ \\ \theta & \Longrightarrow X_1, X_2, \dots, X_n \Longrightarrow & \hat{\theta} \end{array}$ 

- **→** → **→** 

## Method of maximum likelihood

Mathematical statistics

æ

Let  $X_1, X_2, ..., X_n$  be a random sample of size *n* from a distribution with density function  $f_X(x)$ .

Then the density of the joint distribution of  $(X_1, X_2, ..., X_n)$  is

$$f_{joint}(x_1, x_2, \ldots, x_n) = \prod_{i=1}^n f_X(x_i)$$

## Maximum likelihood estimator

• Let  $X_1, X_2, ..., X_n$  have joint pmf or pdf

$$f_{joint}(x_1, x_2, \ldots, x_n; \theta)$$

where  $\theta$  is unknown.

- When x<sub>1</sub>,..., x<sub>n</sub> are the observed sample values and this expression is regarded as a function of θ, it is called the likelihood function.
- The maximum likelihood estimates  $\theta_{ML}$  are the value for  $\theta$  that maximize the likelihood function:

$$f_{joint}(x_1, x_2, \dots, x_n; \theta_{ML}) \ge f_{joint}(x_1, x_2, \dots, x_n; \theta) \quad \forall \theta$$

- Step 1: Write down the likelihood function.
- Step 2: Can you find the maximum of this function?
- Step 3: Try taking the logarithm of this function.
- Step 4: Find the maximum of this new function.

To find the maximum of a function of  $\theta$ :

- $\bullet\,$  compute the derivative of the function with respect to  $\theta\,$
- set this expression of the derivative to 0
- solve the equation

### Problem

Let  $X_1, \ldots, X_n$  be a random sample from the normal distribution  $\mathcal{N}(0, \sigma^2)$ , that is

$$f(x,\theta) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{x^2}{2\sigma^2}}$$

Use the method of maximum likelihood to obtain an estimator of  $\sigma$  (as a function of the data  $x_1, x_2, \ldots, x_n$ ).

### Problem

Let  $\beta > 1$  and  $X_1, \ldots, X_n$  be a random sample from a distribution with pdf

$$f(x) = egin{cases} rac{eta}{x^{eta+1}} & ext{if } x > 1 \ 0 & ext{otherwise} \end{cases}$$

Use the method of maximum likelihood to obtain an estimator of  $\beta$ .

- **→** → **→** 

## Sufficient statistic

Mathematical statistics

æ

・聞き ・ ほき・ ・ ほき

• Your professor stores a dataset  $x_1, x_2, ..., x_n$  in his computer. He says it is a random sample from the exponential distribution

$$f_X(x) = \lambda e^{-\lambda x}, \quad x \ge 0$$

where  $\lambda$  is an unknown parameter. He wants you to work on the dataset and give him a good estimate of  $\lambda$ 

- Assume that the sample size is very large,  $n = 10^{20}$ , and you could not copy the whole dataset
- You can compute any summary statistics of the dataset using the computer, but the lab is closing in 5 minutes
- What will you do?

• If you are using the method of moments

$$\bar{x} = \frac{x_1 + x_2 + \ldots + x_n}{n}$$

• If you are using the method of maximum likelihood

$$L(\lambda) = \lambda^n e^{-\lambda(x_1 + x_2 + \dots + x_n)}$$

• In both case, it seems that you need to only save *n* and  $t = x_1 + x_2 + \ldots + x_n$ 

• For discrete random variables, the conditional probability mass function of Y given the occurrence of the value x of X can be written according to its definition as:

$$P(Y = y | X = x) = \frac{P(Y = y, X = x)}{P(X = x)}$$

• For continuous random variables, the conditional probability of Y given the occurrence of the value x of X has density function

$$f_Y(y|X=x) = \frac{f_{joint}(y,x)}{f(x)}$$

- Basic estimation problem:
  - Given a density function  $f(x, \theta)$  and a sample  $X_1, X_2, \ldots, X_n$
  - Construct a statistic  $\hat{\theta} = T(X_1, X_2, \dots, X_n)$
  - Different statistic *t* leads different estimate, different accuracies
- If, however, the distribution of t(X<sub>1</sub>, X<sub>2</sub>,..., X<sub>n</sub>) does not depend on θ, then it is no good
- Similarly, if the conditional probability

$$P(X_1, X_2, \ldots, X_n | T)$$

does not depend on  $\theta$ , then this means that  $T(X_1, X_2, \dots, X_n)$  contained all the information to estimate  $\theta$ 

#### Definition

A statistic  $T = t(X_1, ..., X_n)$  is said to be sufficient for making inferences about a parameter  $\theta$  if the joint distribution of  $X_1, X_2, ..., X_n$  given that T = t does not depend upon  $\theta$  for every possible value t of the statistic T.

#### Theorem

*T* is sufficient for if and only if nonnegative functions g and h can be found such that

$$f(x_1, x_2, \ldots, x_n; \theta) = g(t(x_1, x_2, \ldots, x_n), \theta) \cdot h(x_1, x_2, \ldots, x_n)$$

i.e. the joint density can be factored into a product such that one factor, h does not depend on  $\theta$ ; and the other factor, which does depend on  $\theta$ , depends on x only through t(x).

 Let X<sub>1</sub>, X<sub>2</sub>, ..., X<sub>n</sub> be a random sample of from a Poisson distribution with parameter λ

$$f(x,\lambda) = \frac{1}{x!}e^{-\lambda x} \qquad x = 0, 1, 2, \dots,$$

where  $\lambda$  is unknown.

• Find a sufficient statistic of  $\lambda$ .

#### Definition

The *m* statistics  $T_1 = t_1(X_1, \ldots, X_n)$ ,  $T_2 = t_2(X_1, \ldots, X_n)$ , ...,  $T_m = t_m(X_1, \ldots, X_n)$  are said to be jointly sufficient for the parameters  $\theta_1, \theta_2, \ldots, \theta_k$  if the joint distribution of  $X_1, X_2, \ldots, X_n$  given that

$$T_1=t_1, T_2=t_2,\ldots, T_m=t_m$$

does not depend upon  $\theta_1, \theta_2, \ldots, \theta_k$  for every possible value  $t_1, t_2, \ldots, t_m$  of the statistics.

#### Theorem

 $T_1, T_2, \ldots, T_m$  are sufficient for  $\theta_1, \theta_2, \ldots, \theta_k$  if and only if nonnegative functions g and h can be found such that

$$f(x_1, x_2, \ldots, x_n; \theta_1, \theta_2, \ldots, \theta_k) = g(t_1, t_2, \ldots, t_m, \theta_1, \theta_2, \ldots, \theta_k)$$
$$\cdot h(x_1, x_2, \ldots, x_n)$$

• Let  $X_1, X_2, ..., X_n$  be a random sample from  $\mathcal{N}(\mu, \sigma^2)$ 

$$f_X(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

Prove that

$$T_1 = X_1 + \ldots + X_n, \qquad T_2 = X_1^2 + X_2^2 + \ldots + X_n^2$$

are jointly sufficient for the two parameters  $\mu$  and  $\sigma$ .

• Let  $X_1, X_2, ..., X_n$  be a random sample from a Gamma distribution

$$f_X(x) = \frac{1}{\Gamma(\alpha)\beta^{\alpha}} x^{\alpha-1} e^{-x/\beta}$$

where  $\alpha, \beta$  is unknown.

Prove that

$$T_1=X_1+\ldots+X_n, \qquad T_2=\prod_{i=1}^n X_i$$

are jointly sufficient for the two parameters  $\alpha$  and  $\beta$ .
