# Mathematical statistics 

November $8^{\text {th }}, 2018$<br>Lecture 19: P-values

## Overview

9.1 Hypotheses and test procedures

- test procedures
- errors in hypothesis testing
- significance level
9.2 Tests about a population mean
- normal population with known $\sigma$
- large-sample tests
- a normal population with unknown $\sigma$
9.4 P-values
9.3 Tests concerning a population proportion
9.5 Selecting a test procedure

Hypothesis testing

4ロ〉4甸〉（

っのく

## Hypothesis testing

In any hypothesis-testing problem, there are two contradictory hypotheses under consideration

- The null hypothesis, denoted by $H_{0}$, is the claim that is initially assumed to be true
- The alternative hypothesis, denoted by $H_{a}$, is the assertion that is contradictory to $\mathrm{H}_{0}$.

## Implicit rules (of this chapter)

- $H_{0}$ will always be stated as an equality claim.
- If $\theta$ denotes the parameter of interest, the null hypothesis will have the form

$$
H_{0}: \theta=\theta_{0}
$$

- $\theta_{0}$ is a specified number called the null value
- The alternative hypothesis will be either:
- $H_{a}: \theta>\theta_{0}$
- $H_{a}: \theta<\theta_{0}$
- $H_{a}: \theta \neq \theta_{0}$

A test procedure is specified by the following:

- A test statistic $T$ : a function of the sample data on which the decision (reject $H_{0}$ or do not reject $H_{0}$ ) is to be based
- A rejection region $\mathcal{R}$ : the set of all test statistic values for which $H_{0}$ will be rejected

The null hypothesis will then be rejected if and only if the observed or computed test statistic value falls in the rejection region, i.e., $T \in \mathcal{R}$

- A type I error consists of rejecting the null hypothesis $H_{0}$ when it is true
- A type II error involves not rejecting $H_{0}$ when $H_{0}$ is false.

The approach adhered to by most statistical practitioners is

- specify the largest value of $\alpha$ that can be tolerated
- find a rejection region having that value of $\alpha$ rather than anything smaller
- $\alpha$ : the significance level of the test
- the corresponding test procedure is called a level $\alpha$ test

## Hypothesis testing for one parameter

(1) Identify the parameter of interest
(2) Determine the null value and state the null hypothesis
(3) State the appropriate alternative hypothesis
(9) Give the formula for the test statistic
(5) State the rejection region for the selected significance level $\alpha$
(0) Compute statistic value from data
( ( Decide whether $H_{0}$ should be rejected and state this conclusion in the problem context

## Tests about a population mean

- Null hypothesis

$$
H_{0}: \mu=\mu_{0}
$$

- The alternative hypothesis will be either:
- $H_{a}: \mu>\mu_{0}$
- $H_{a}: \mu<\mu_{0}$
- $H_{a}: \mu \neq \mu_{0}$
- Three settings
- normal population with known $\sigma$
- large-sample tests
- a normal population with unknown $\sigma$

## Normal population with known $\sigma$

Null hypothesis: $\mu=\mu_{0}$
Test statistic:

$$
Z=\frac{\bar{X}-\mu_{0}}{\sigma / \sqrt{n}}
$$

## Alternative Hypothesis

$H_{\mathrm{a}}: \mu>\mu_{0}$
$H_{\mathrm{a}}: \mu<\mu_{0}$
$H_{\mathrm{a}}: \mu \neq \mu_{0}$

Rejection Region for Level $\alpha$ Test
$z \geq z_{\alpha}$ (upper-tailed test)
$z \leq-z_{\alpha}$ (lower-tailed test)
either $z \geq z_{\alpha / 2}$ or $z \leq-z_{\alpha / 2}$ (two-tailed test)

## General rule

$z$ curve (probability distribution of test statistic $Z$ when $H_{0}$ is true)

## Example

## Problem

A manufacturer of sprinkler systems used for fire protection in office buildings claims that the true average system-activation temperature is $130^{\circ} F$. A sample of $n=9$ systems, when tested, yields a sample average activation temperature of $131.08^{\circ} \mathrm{F}$.

If the distribution of activation times is normal with standard deviation $1.5^{\circ} \mathrm{F}$, does the data contradict the manufacturers claim at significance level $\alpha=0.01$ ?

- Parameter of interest: $\mu=$ true average activation temperature
- Hypotheses

$$
\begin{aligned}
& H_{0}: \mu=130 \\
& H_{a}: \mu \neq 130
\end{aligned}
$$

- Test statistic:

$$
z=\frac{\bar{x}-130}{1.5 / \sqrt{n}}
$$

- Rejection region: either $z \leq-z_{0.005}$ or $z \geq z_{0.005}=2.58$
- Substituting $\bar{x}=131.08, n=25 \rightarrow z=2.16$.
- Note that $-2.58<2.16<2.58$. We fail to reject $H_{0}$ at significance level 0.01 .
- The data does not give strong support to the claim that the true average differs from the design value.

## Large-sample tests

Null hypothesis: $\mu=\mu_{0}$
Test statistic:

$$
Z=\frac{\bar{X}-\mu_{0}}{S / \sqrt{n}}
$$

## Alternative Hypothesis

$H_{\mathrm{a}}: \mu>\mu_{0}$
$H_{\mathrm{a}}: \mu<\mu_{0}$
$H_{\mathrm{a}}: \mu \neq \mu_{0}$

Rejection Region for Level $\alpha$ Test
$z \geq z_{\alpha}$ (upper-tailed test)
$z \leq-z_{\alpha}$ (lower-tailed test)
either $z \geq z_{\alpha / 2}$ or $z \leq-z_{\alpha / 2}$ (two-tailed test)
[Does not need the normal assumption]

Null hypothesis: $H_{0}: \mu=\mu_{0}$
Test statistic value: $t=\frac{\bar{x}-\mu_{0}}{s / \sqrt{n}}$
Alternative Hypothesis

## Rejection Region for a Level $\alpha$ Test

$H_{\mathrm{a}}: \mu>\mu_{0}$
$H_{\mathrm{a}}: \mu<\mu_{0}$
$H_{\mathrm{a}}: \mu \neq \mu_{0}$

$$
\begin{aligned}
& t \geq t_{\alpha, n-1} \text { (upper-tailed) } \\
& t \leq-t_{\alpha, n-1} \text { (lower-tailed) }
\end{aligned}
$$

$$
\text { either } t \geq t_{\alpha / 2, n-1} \text { or } t \leq-t_{\alpha / 2, n-1} \text { (two-tailed) }
$$

[Require normal assumption]

## Example

## Problem

The amount of shaft wear (. 0001 in .) after a fixed mileage was determined for each of $n=8$ internal combustion engines having copper lead as a bearing material, resulting in $\bar{x}=3.72$ and $s=1.25$.
Assuming that the distribution of shaft wear is normal with mean $\mu$, use the t-test at level 0.05 to test $H_{0}: \mu=3.5$ versus $H_{a}: \mu>3.5$.

Mathematical statistics

## Practice

## Problem

The standard thickness for silicon wafers used in a certain type of integrated circuit is $245 \mu \mathrm{~m}$. A sample of 50 wafers is obtained and the thickness of each one is determined, resulting in a sample mean thickness of $246.18 \mu \mathrm{~m}$ and a sample standard deviation of $3.60 \mu \mathrm{~m}$.
Does this data suggest that true average wafer thickness is larger than the target value? Carry out a test of significance at level . 05 .

## P-values

## Remarks

- The common approach in statistical testing is:
(1) specifying significance level $\alpha$
(2) reject/not reject $H_{0}$ based on evidence
- Weaknesses of this approach:
- it says nothing about whether the computed value of the test statistic just barely fell into the rejection region or whether it exceeded the critical value by a large amount
- each individual may select their own significance level for their presentation
- We also want to include some objective quantity that describes how strong the rejection is $\rightarrow \mathrm{P}$-value

## Practice problem

## Problem

Suppose $\mu$ was the true average nicotine content of brand of cigarettes. We want to test:

$$
\begin{aligned}
& H_{0}: \mu=1.5 \\
& H_{a}: \mu>1.5
\end{aligned}
$$

Suppose that $n=64$ and $z=\frac{\bar{x}-1.5}{s / \sqrt{n}}=2.1$. Will we reject $H_{0}$ if the significance level is
(a) $\alpha=0.05$
(b) $\alpha=0.025$
(c) $\alpha=0.01$
(d) $\alpha=0.005$

Mathematical statistics

## P-value

| Level of <br> Significance $\boldsymbol{\alpha}$ | Rejection <br> Region | Conclusion |
| :--- | :---: | :--- |
| .05 | $z \geq 1.645$ | Reject $H_{0}$ |
| .025 | $z \geq 1.96$ | Reject $H_{0}$ |
| .01 | $z \geq 2.33$ | Do not reect $H_{0}$ |
| .005 | $z \geq 2.58$ | Do not reject $H_{0}$ |

Question: What is the smallest value of $\alpha$ for which $H_{0}$ is rejected.

## P-value

DEFINITION The $\boldsymbol{P}$-value (or observed significance level) is the smallest level of significance at which $H_{0}$ would be rejected when a specified test procedure is used on a given data set. Once the $P$-value has been determined, the conclusion at any particular level $\alpha$ results from comparing the $P$-value to $\alpha$ :

1. $P$-value $\leq \alpha \Rightarrow$ reject $H_{0}$ at level $\alpha$.
2. $P$-value $>\alpha \Rightarrow$ do not reject $H_{0}$ at level $\alpha$.

DECISION
RULE BASED
ON THE
$P$-VALUE

Select a significance level $\alpha$ (as before, the desired type I error probability).
Then reject $H_{0}$ if $P$-value $\leq \alpha$; do not reject $H_{0}$ if $P$-value $>\alpha$

Remark: the smaller the P -value, the more evidence there is in the sample data against the null hypothesis and for the alternative hypothesis.

## P-values for z-tests

Figure 9.7 Determination of the $P$-value for a $z$ test

## Practice problem

## Problem

The target thickness for silicon wafers used in a certain type of integrated circuit is $245 \mu \mathrm{~m}$. A sample of 50 wafers is obtained and the thickness of each one is determined, resulting in a sample mean thickness of $246.18 \mu \mathrm{~m}$ and a sample standard deviation of $3.60 \mu \mathrm{~m}$.
Does this data suggest that true average wafer thickness is something other than the target value?

Mathematical statistics

## P-values for z-tests

1. Parameter of interest: $\mu=$ true average wafer thickness
2. Null hypothesis: $\quad H_{0}: \quad \mu=245$
3. Alternative hypothesis: $\quad H_{\mathrm{a}}: \quad \mu \neq 245$
4. Formula for test statistic value: $z=\frac{\bar{x}-245}{s / \sqrt{n}}$
5. Calculation of test statistic value: $\quad z=\frac{246.18-245}{3.60 / \sqrt{50}}=2.32$
6. Determination of $P$-value: Because the test is two-tailed,

$$
P \text {-value }=2[1-\Phi(2.32)]=.0204
$$

7. Conclusion: Using a significance level of $.01, H_{0}$ would not be rejected since $.0204>.01$. At this significance level, there is insufficient evidence to conclude that true average thickness differs from the target value.

## P-values for z-tests

$$
P \text {-value: } \quad P= \begin{cases}1-\Phi(z) & \text { for an upper-tailed test } \\ \Phi(z) & \text { for a lower-tailed test } \\ 2[1-\Phi(|z|)] & \text { for a two-tailed test }\end{cases}
$$

## P-values for $t$-tests

Figure $9.8 P$-values for $t$ tests

## Practice problem

## Problem

Suppose we want to test

$$
\begin{aligned}
& H_{0}: \mu=25 \\
& H_{a}: \mu>25
\end{aligned}
$$

from a sample with $n=5$ and the calculated value

$$
t=\frac{\bar{x}-25}{s / \sqrt{n}}=1.02
$$

(a) What is the $P$-value of the test
(b) Should we reject the null hypothesis?

## Interpreting P-values

A P-value:

- is not the probability that $H_{0}$ is true
- is not the probability of rejecting $H_{0}$
- is the probability, calculated assuming that $H_{0}$ is true, of obtaining a test statistic value at least as contradictory to the null hypothesis as the value that actually resulted

THAT SETLES THAT.
I HEAR IT'S ONLY A CERTAIN COLOR that causes it.
