Lecture 20: Intervals based on normal distributions

## 8.1 Basic properties of confidence intervals (CIs)

- Interpreting CIs
- General principles to derive CI

## 8.2 Large-sample confidence intervals for a population mean

- Using the Central Limit Theorem to derive CIs

## 8.3 Intervals based on normal distribution

- Using Student's t-distribution

## 8.4 CIs for standard deviation

# Confidence Intervals

- Let  $X_1, X_2, \dots, X_n$  be a random sample from a distribution  $f(x, \theta)$
- In Chapter 7, we learnt methods to construct an estimate  $\hat{\theta}$  of  $\theta$
- Goal: we want to indicate the degree of uncertainty associated with this random prediction
- One way to do so is to construct a *confidence interval*  $[\hat{\theta} - a, \hat{\theta} + b]$  such that

$$P[\theta \in [\hat{\theta} - a, \hat{\theta} + b]] = 95\%$$

# Principles for deriving CIs

If  $X_1, X_2, \dots, X_n$  is a random sample from a distribution  $f(x, \theta)$ , then

- Find a random variable  $Y = h(X_1, X_2, \dots, X_n; \theta)$  such that the probability distribution of  $Y$  does not depend on  $\theta$  or on any other unknown parameters.
- Find constants  $a, b$  such that

$$P[a < h(X_1, X_2, \dots, X_n; \theta) < b] = 0.95$$

- Manipulate these inequalities to isolate  $\theta$

$$P[\ell(X_1, X_2, \dots, X_n) < \theta < u(X_1, X_2, \dots, X_n)] = 0.95$$

## 8.1: Normal distribution with known $\sigma$

- Assumptions:
  - Normal distribution
  - $\sigma$  is known
- 95% confidence interval

If after observing  $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$ , ( $n > 40$ ), we compute the observed sample mean  $\bar{x}$ . Then

$$\left( \bar{x} - 1.96 \frac{\sigma}{\sqrt{n}}, \bar{x} + 1.96 \frac{\sigma}{\sqrt{n}} \right)$$

is a 95% confidence interval of  $\mu$

- Section 8.1
  - Normal distribution
  - $\sigma$  is known
- Section 8.2
  - Normal distribution
    - use Central Limit Theorem → needs  $n > 30$
  - $\sigma$  is known
    - replace  $\sigma$  by  $s$  → needs  $n > 40$
- Section 8.3
  - Normal distribution
  - $\sigma$  is known

→ Introducing  $t$ -distribution

# $100(1 - \alpha)\%$ confidence interval

Figure 8.4  $P(-z_{\alpha/2} \leq Z \leq z_{\alpha/2}) = 1 - \alpha$

# $100(1 - \alpha)\%$ confidence interval

A  **$100(1 - \alpha)\%$  confidence interval** for the mean  $\mu$  of a normal population when the value of  $\sigma$  is known is given by

$$\left( \bar{x} - z_{\alpha/2} \cdot \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{\alpha/2} \cdot \frac{\sigma}{\sqrt{n}} \right) \quad (8.5)$$

or, equivalently, by  $\bar{x} \pm z_{\alpha/2} \cdot \sigma / \sqrt{n}$ .

## 8.2: Large-sample CIs of the population mean

- Central Limit Theorem

$$\frac{\bar{X} - \mu}{\sigma/\sqrt{n}}$$

is approximately normal when  $n > 30$

- Moreover, when  $n$  is sufficiently large  $s \approx \sigma$
- Conclusion:

$$\frac{\bar{X} - \mu}{s/\sqrt{n}}$$

is approximately normal when  $n$  is sufficiently large

**If  $n > 40$ , we can ignore the normal assumption and replace  $\sigma$  by  $s$**

# 95% confidence interval

If after observing  $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$ , ( $n > 40$ ), we compute the observed sample mean  $\bar{x}$  and sample standard deviation  $s$ . Then

$$\left( \bar{x} - 1.96 \frac{s}{\sqrt{n}}, \bar{x} + 1.96 \frac{s}{\sqrt{n}} \right)$$

is a 95% confidence interval of  $\mu$

# $100(1 - \alpha)\%$ confidence interval

If after observing  $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$ , ( $n > 40$ ), we compute the observed sample mean  $\bar{x}$  and sample standard deviation  $s$ . Then

$$\left( \bar{x} - z_{\alpha/2} \frac{s}{\sqrt{n}}, \bar{x} + z_{\alpha/2} \frac{s}{\sqrt{n}} \right)$$

is a 95% confidence interval of  $\mu$

## One-sided CIs (Confidence bounds)

**A large-sample upper confidence bound for  $\mu$  is**

$$\mu < \bar{x} + z_{\alpha} \cdot \frac{s}{\sqrt{n}}$$

**and a large-sample lower confidence bound for  $\mu$  is**

$$\mu > \bar{x} - z_{\alpha} \cdot \frac{s}{\sqrt{n}}$$

# CIs vs. one-sided CIs

CIs:

- $100(1 - \alpha)\%$  confidence

$$\left( \bar{x} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$$

- 95% confidence

$$\left( \bar{x} - 1.96 \frac{\sigma}{\sqrt{n}}, \bar{x} + 1.96 \frac{\sigma}{\sqrt{n}} \right)$$

One-sided CIs:

- $100(1 - \alpha)\%$  confidence

$$\left( -\infty, \bar{x} + z_{\alpha} \frac{\sigma}{\sqrt{n}} \right)$$

- 95% confidence

$$\left( -\infty, \bar{x} + 1.64 \frac{\sigma}{\sqrt{n}} \right)$$

## Problem

*Determine the confidence level for each of the following large-sample confidence intervals/bounds:*

(a)  $\bar{x} + 0.84s/\sqrt{n}$

(b)  $(\bar{x} - 0.84s/\sqrt{n}, \bar{x} + 0.84s/\sqrt{n})$

(c)  $\bar{x} - 2.05s/\sqrt{n}$

## 8.3: Intervals based on normal distributions

- the population of interest is normal  
(i.e.,  $X_1, \dots, X_n$  constitutes a random sample from a normal distribution  $\mathcal{N}(\mu, \sigma^2)$ ).
- $\sigma$  is unknown

→ we want to consider cases when  $n$  is small.

- When  $n < 40$ ,  $S$  is no longer close to  $\sigma$ . Thus

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}}$$

does not follow the standard normal distribution.

- {Section 6} But since we know the distribution of  $X$ , technically we can compute the distribution of  $T$
- Moreover, the distribution of  $T$  does not depend on  $\mu$  and  $\sigma$   
{More reading: Section 6.4}

# $t$ distributions with degree of freedom $\nu$

Probability density function

$$f(t) = \frac{\Gamma(\frac{\nu+1}{2})}{\sqrt{\nu\pi} \Gamma(\frac{\nu}{2})} \left(1 + \frac{t^2}{\nu}\right)^{-\frac{\nu+1}{2}}$$

## PROPERTIES OF $T$ DISTRI- BUTIONS

1. Each  $t_\nu$  curve is bell-shaped and centered at 0.
2. Each  $t_\nu$  curve is more spread out than the standard normal ( $z$ ) curve.
3. As  $\nu$  increases, the spread of the  $t_\nu$  curve decreases.
4. As  $\nu \rightarrow \infty$ , the sequence of  $t_\nu$  curves approaches the standard normal curve (so the  $z$  curve is often called the  $t$  curve with  $df = \infty$ ).

When  $\bar{X}$  is the mean of a random sample of size  $n$  from a normal distribution with mean  $\mu$ , the rv

$$\frac{\bar{X} - \mu}{S/\sqrt{n}}$$

has the  $t$  distribution with  $n - 1$  degree of freedom (df).

# $t$ distributions

Let  $t_{\alpha, \nu}$  = the number on the measurement axis for which the area under the  $t$  curve with  $\nu$  df to the right of  $t_{\alpha, \nu}$ , is  $\alpha$ ;  $t_{\alpha, \nu}$  is called a  **$t$  critical value**.

Figure 8.7 A pictorial definition of  $t_{\alpha, \nu}$

# How to do computation with $t$ distributions

- Instead of looking up the normal  $Z$ -table A3, look up the two  $t$ -tables A5 and A7.
- Idea

$$P[T \geq t_{\alpha, \nu}] = \alpha$$

- {From  $t$ , find  $\alpha$ }  $\rightarrow$  using table A7
- {From  $\alpha$ , find  $t$ }  $\rightarrow$  using table A5

**Table A.7**  $t$  Curve Tail Areas

# Confidence intervals

Let  $\bar{x}$  and  $s$  be the sample mean and sample standard deviation computed from the results of a random sample from a normal population with mean  $\mu$ . Then a **100(1 -  $\alpha$ )% confidence interval for  $\mu$ , the one-sample  $t$  CI**, is

$$\left( \bar{x} - t_{\alpha/2, n-1} \cdot \frac{s}{\sqrt{n}}, \bar{x} + t_{\alpha/2, n-1} \cdot \frac{s}{\sqrt{n}} \right) \quad (8.15)$$

or, more compactly,  $\bar{x} \pm t_{\alpha/2, n-1} \cdot s/\sqrt{n}$ .

An **upper confidence bound for  $\mu$**  is

$$\bar{x} + t_{\alpha, n-1} \cdot \frac{s}{\sqrt{n}}$$

and replacing + by - in this latter expression gives a **lower confidence bound for  $\mu$** ; both have confidence level 100(1 -  $\alpha$ )%.

## Practice problem

- 31.** Determine the  $t$  critical value for a two-sided confidence interval in each of the following situations:
- a.** Confidence level = 95%,  $df = 10$

# Prediction intervals

# Principles for deriving CIs

If  $X_1, X_2, \dots, X_n$  is a random sample from a distribution  $f(x, \theta)$ , then

- Find a random variable  $Y = h(X_1, X_2, \dots, X_n; \theta)$  such that the probability distribution of  $Y$  does not depend on  $\theta$  or on any other unknown parameters.
- Find constants  $a, b$  such that

$$P[a < h(X_1, X_2, \dots, X_n; \theta) < b] = 0.95$$

- Manipulate these inequalities to isolate  $\theta$

$$P[\ell(X_1, X_2, \dots, X_n) < \theta < u(X_1, X_2, \dots, X_n)] = 0.95$$

- We have available a random sample  $X_1, X_2, \dots, X_n$  from a normal population distribution
- We wish to predict the value of  $X_{n+1}$ , a single future observation.

This is a much more difficult problem than the problem of estimating  $\mu$

- When  $n \rightarrow \infty$ ,  $\bar{X} \rightarrow \mu$
- Even when we know  $\mu$ ,  $X_{n+1}$  is still random

A natural estimate of  $X_{n+1}$  is

$$\bar{X} = \frac{X_1 + \dots + X_n}{n}$$

Question: What is the uncertainty of this estimate?

Let  $X_1, X_2, \dots, X_n$  be a sample from a normal population distribution  $\mathcal{N}(\mu, \sigma)$  and  $X_{n+1}$  be an independent sample from the same distribution.

- Compute  $E[\bar{X} - X_{n+1}]$  in terms of  $\mu, \sigma, n$
- Compute  $Var[\bar{X} - X_{n+1}]$  in terms of  $\mu, \sigma, n$
- What is the distribution of  $\bar{X} - X_{n+1}$ ?

If  $\sigma$  is known

$$\frac{\bar{X} - X_{n+1}}{\sigma \sqrt{1 + \frac{1}{n}}}$$

follows the standard normal distribution  $\mathcal{N}(0, 1)$ .

$$T = \frac{\bar{X} - X_{n+1}}{S\sqrt{1 + \frac{1}{n}}} \sim t \text{ distribution with } n - 1 \text{ df}$$

A **prediction interval (PI)** for a single observation to be selected from a normal population distribution is

$$\bar{x} \pm t_{\alpha/2, n-1} \cdot s \sqrt{1 + \frac{1}{n}} \quad (8.16)$$

The *prediction level* is  $100(1 - \alpha)\%$ .

## Practice problem

- 31.** Determine the  $t$  critical value for a two-sided confidence interval in each of the following situations:
- a.** Confidence level = 95%,  $df = 10$
  - b.** Confidence level = 95%,  $df = 15$

$$\alpha \rightarrow t$$

**Table A.5** Critical Values for  $t$  Distributions

		$\alpha$						
$\nu$	.10	.05	.025	.01	.005	.001	.0005

8	1.397	1.860	2.306	2.896	3.355	4.501	5.041	
9	1.383	1.833	2.262	2.821	3.250	4.297	4.781	
10	1.372	1.812	2.228	2.764	3.169	4.144	4.587	
11	1.363	1.796	2.201	2.718	3.106	4.025	4.437	
12	1.356	1.782	2.179	2.681	3.055	3.930	4.318	
13	1.350	1.771	2.160	2.650	3.012	3.852	4.221	
14	1.345	1.761	2.145	2.624	2.977	3.787	4.140	
15	1.341	1.753	2.131	2.602	2.947	3.733	4.073	
16	1.337	1.746	2.120	2.583	2.921	3.686	4.015	
17	1.333	1.740	2.110	2.567	2.898	3.646	3.965	

Here are the lengths (in minutes) of the 63 nine-inning games from the first week of the 2001 major league baseball season:

194	160	176	203	187	163	162	183	152	177
177	151	173	188	179	194	149	165	186	187
187	177	187	186	187	173	136	150	173	173
136	153	152	149	152	180	186	166	174	176
198	193	218	173	144	148	174	163	184	155
151	172	216	149	207	212	216	166	190	165
176	158	198							

Assume that this is a random sample of nine-inning games (the mean differs by 12 s from the mean for the whole season).

- Give a 95% confidence interval for the population mean.
- Give a 95% prediction interval for the length of the next nine-inning game. On the first day of the next week, Boston beat Tampa Bay 3–0 in a nine-inning game of 152 min. Is this within the prediction interval?

## Section 6.4: Distributions based on a normal random sample

- The Chi-squared distribution
- The  $t$  distribution
- The  $F$  Distribution

# Chi-squared distribution

The pdf of a Chi-squared distribution with degree of freedom  $\nu$ , denoted by  $\chi_{\nu}^2$ , is

$$f(x) = \begin{cases} \frac{1}{2^{1/2}\Gamma(\nu/2)} x^{(\nu/2)-1} e^{-x/2} & x > 0 \\ 0 & x \leq 0 \end{cases}$$

# Why is Chi-squared useful?

## Proposition

*If  $Z$  has standard normal distribution  $\mathcal{Z}(0, 1)$  and  $X = Z^2$ , then  $X$  has Chi-squared distribution with 1 degree of freedom, i.e.  $X \sim \chi_1^2$  distribution.*

## Proposition

*If  $X_1 \sim \chi_{\nu_1}^2$ ,  $X_2 \sim \chi_{\nu_2}^2$  and they are independent, then*

$$X_1 + X_2 \sim \chi_{\nu_1 + \nu_2}^2$$

# Why is Chi-squared useful?

## Proposition

*If  $Z_1, Z_2, \dots, Z_n$  are independent and each has the standard normal distribution, then*

$$Z_1^2 + Z_2^2 + \dots + Z_n^2 \sim \chi_n^2$$

# Why is Chi-squared useful?

If  $X_1, X_2, \dots, X_n$  is a random sample from the normal distribution  $\mathcal{N}(\mu, \sigma^2)$ . Note that

$$\sum \left( \frac{X_i - \mu}{\sigma} \right)^2 = \sum \left( \frac{X_i - \bar{X}}{\sigma} \right)^2 + \left( \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \right)^2 = \frac{(n-1)S^2}{\sigma^2} + \left( \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \right)^2$$

- What is the distribution of the LHS?
- What is the distribution of the second term on the RHS?
- What is the distribution of

$$(n-1) \frac{S^2}{\sigma^2}$$

# Why is Chi-squared useful?

If  $X_1, X_2, \dots, X_n$  is a random sample from the normal distribution  $\mathcal{N}(\mu, \sigma^2)$ , then

$$(n-1) \frac{S^2}{\sigma^2} \sim \chi_{n-1}^2$$

Let  $Z$  be a standard normal rv and let  $X$  be a  $\chi^2_\nu$  rv independent of  $Z$ . Then the  $t$  distribution with degrees of freedom  $\nu$  is defined to be the distribution of the ratio

$$T = \frac{Z}{\sqrt{X/\nu}}$$

When  $\bar{X}$  is the mean of a random sample of size  $n$  from a normal distribution with mean  $\mu$ , the rv

$$\frac{\bar{X} - \mu}{S/\sqrt{n}}$$

has the  $t$  distribution with  $n - 1$  degree of freedom (df).

Hint:

$$T = \frac{Z}{\sqrt{X/\nu}} \quad (n-1) \frac{S^2}{\sigma^2} \sim \chi_{n-1}^2$$

and

$$\frac{\bar{X} - \mu}{S/\sqrt{n}} = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \cdot \frac{1}{\sqrt{(n-1) \frac{S^2}{\sigma^2} / (n-1)}}.$$

Let  $X_1$  and  $X_2$  be independent chi-squared random variables with  $\nu_1$  and  $\nu_2$  degrees of freedom, respectively. The  $F_{\nu_1, \nu_2}$  distribution with  $\nu_1$  numerator degrees of freedom and  $\nu_2$  denominator degrees of freedom is defined to be the distribution of the ratio

$$\frac{X_1/\nu_1}{X_2/\nu_2}$$

## CIs for variance and standard deviation

# Why is Chi-squared useful?

If  $X_1, X_2, \dots, X_n$  is a random sample from the normal distribution  $\mathcal{N}(\mu, \sigma^2)$ , then

$$(n - 1) \frac{S^2}{\sigma^2} \sim \chi_{n-1}^2$$

# Important: Chi-squared distribution are not symmetric

We have

$$P\left(\chi_{1-\alpha/2, n-1}^2 < \frac{(n-1)S^2}{\sigma^2} < \chi_{\alpha/2, n-1}^2\right) = 1 - \alpha$$

Play around with these inequalities:

$$\frac{(n-1)S^2}{\chi_{\alpha/2, n-1}^2} < \sigma^2 < \frac{(n-1)S^2}{\chi_{1-\alpha/2, n-1}^2}$$

A **100(1 -  $\alpha$ )% confidence interval for the variance  $\sigma^2$  of a normal population** has lower limit

$$(n - 1)s^2 / \chi_{\alpha/2, n-1}^2$$

and upper limit

$$(n - 1)s^2 / \chi_{1-\alpha/2, n-1}^2$$

A **confidence interval for  $\sigma$**  has lower and upper limits that are the square roots of the corresponding limits in the interval for  $\sigma^2$ .
