## Chapter 6: Statistics and Sampling Distributions

Mathematical statistics

- 6.1 Statistics and their distributions
- 6.2 The distribution of the sample mean
- 6.3 The distribution of a linear combination

The random variables  $X_1, X_2, ..., X_n$  are said to form a (simple) random sample of size n if

- the  $X_i$ 's are independent random variables
- **2** every  $X_i$  has the same probability distribution

/⊒ ► < ∃ ►

- If the distribution and the statistic T is simple, try to construct the pmf of the statistic
- **2** If the probability density function  $f_X(x)$  of X's is known, the
  - try to represent/compute the cumulative distribution (cdf) of  ${\cal T}$

$$\mathbb{P}[T \leq t]$$

• take the derivative of the function (with respect to t)

#### Theorem

Let  $X_1, X_2, ..., X_n$  be independent normal random variables (with possibly different means and/or variances). Then

$$T = a_1 X_1 + a_2 X_2 + \ldots + a_n X_n$$

also follows the normal distribution.

# Section 6.3: Computations with normal random variables

If X has a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ , then

$$Z = \frac{X - \mu}{\sigma}$$

has a standard normal distribution. Thus

$$P(a \le X \le b) = P\left(\frac{a-\mu}{\sigma} \le Z \le \frac{b-\mu}{\sigma}\right)$$
$$= \Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)$$
$$P(X \le a) = \Phi\left(\frac{a-\mu}{\sigma}\right) \quad P(X \ge b) = 1 - \Phi\left(\frac{b-\mu}{\sigma}\right)$$

#### Theorem

Let  $X_1, X_2, \ldots, X_n$  be independent random variables (with possibly different means and/or variances). Define

$$T = a_1 X_1 + a_2 X_2 + \ldots + a_n X_n,$$

then the mean and the standard deviation of T can be computed by

• 
$$E(T) = a_1 E(X_1) + a_2 E(X_2) + \ldots + a_n E(X_n)$$

• 
$$\sigma_T^2 = a_1^2 \sigma_{X_1}^2 + a_2^2 \sigma_{X_2}^2 + \ldots + a_n^2 \sigma_{X_n}^2$$

#### Theorem

Let  $X_1, X_2, \ldots, X_n$  be a random sample from a distribution with mean  $\mu$  and variance  $\sigma^2$ . Then, in the limit when  $n \to \infty$ , the standardized version of  $\overline{X}$  have the standard normal distribution

$$\lim_{n\to\infty} \mathbb{P}\left(\frac{\bar{X}-\mu}{\sigma/\sqrt{n}} \leq z\right) = \mathbb{P}[Z \leq z] = \Phi(z)$$

Rule of Thumb:

If n > 30, the Central Limit Theorem can be used for computation.

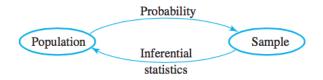

## Chapter 7: Point Estimation

Mathematical statistics

æ

▲ 伊 ▶ ▲ 王 ▶

- 7.1 Point estimate
  - unbiased estimator
  - mean squared error
- 7.2 Methods of point estimation
  - method of moments
  - method of maximum likelihood.

A point estimate  $\hat{\theta}$  of a parameter  $\theta$  is a single number that can be regarded as a sensible value for  $\theta$ .

< 同 > < 回 > < 回 > -

The mean squared error of an estimator  $\hat{\theta}$  is

$$E[(\hat{\theta}-\theta)^2]$$

#### Theorem

$$MSE(\hat{\theta}) = E[(\hat{\theta} - \theta)^2] = V(\hat{\theta}) + (E(\hat{\theta}) - \theta)^2$$

### **Bias-variance decomposition**

Mean squared error = variance of estimator +  $(bias)^2$ 

A point estimator  $\hat{\theta}$  is said to be an unbiased estimator of  $\theta$  if

$$E(\hat{\theta}) = \theta$$

for every possible value of  $\theta$ .

Unbiased estimator  $\Leftrightarrow$  Bias = 0  $\Leftrightarrow$  Mean squared error = variance of estimator

### Problem

Consider a random sample  $X_1, \ldots, X_n$  from the pdf

$$f(x) = rac{1+ heta x}{2} \qquad -1 \leq x \leq 1$$

Show that  $\hat{\theta} = 3\bar{X}$  is an unbiased estimator of  $\theta$ .

▲ 伊 ▶ ▲ 王 ▶

• Let  $X_1, \ldots, X_n$  be a random sample from a distribution with pmf or pdf

$$f(x; \theta_1, \theta_2, \ldots, \theta_m)$$

• Assume that for  $k = 1, \ldots, m$ 

$$\frac{X_1^k + X_2^k + \ldots + X_n^k}{n} = E(X^k)$$

• Solve the system of equations for  $\theta_1, \theta_2, \ldots, \theta_m$ 

#### Problem

Suppose that for a parameter  $0 \le \theta \le 1$ , X is the outcome of the roll of a four-sided tetrahedral die

Suppose the die is rolled 10 times with outcomes

4, 1, 2, 3, 1, 2, 3, 4, 2, 3

Use the method of moments to obtain an estimator of  $\theta$ .

## Midterm: Problem 2a

#### Problem

Let  $X_1, X_2, \ldots, X_n$  represent a random sample from a distribution with pdf

$$f(x,\theta) = \frac{2x}{\theta+1}e^{-x^2/(\theta+1)}, \quad x > 0$$

It can be shown that

$$E(X^2-1)=\theta$$

Use this fact to construct an estimator of  $\theta$  based on the method of moments.

Sketch:

$$E(X^2)=\theta-1$$

MoM:

$$E(X^2) = \frac{X_1^2 + X_2^2 + \ldots + X_n^2}{n}$$

# Maximum likelihood estimator

• Let  $X_1, X_2, ..., X_n$  have joint pmf or pdf

$$f_{joint}(x_1, x_2, \ldots, x_n; \theta)$$

where  $\theta$  is unknown.

- When x<sub>1</sub>,..., x<sub>n</sub> are the observed sample values and this expression is regarded as a function of θ, it is called the likelihood function.
- The maximum likelihood estimates  $\theta_{ML}$  are the value for  $\theta$  that maximize the likelihood function:

$$f_{joint}(x_1, x_2, \dots, x_n; \theta_{ML}) \ge f_{joint}(x_1, x_2, \dots, x_n; \theta) \quad \forall \theta$$

- Step 1: Write down the likelihood function.
- Step 2: Can you find the maximum of this function?
- Step 3: Try taking the logarithm of this function.
- Step 4: Find the maximum of this new function.

To find the maximum of a function of  $\theta$ :

- $\bullet\,$  compute the derivative of the function with respect to  $\theta\,$
- set this expression of the derivative to 0
- solve the equation

#### Problem

Let  $X_1, X_2, \ldots, X_n$  represent a random sample from a distribution with pdf

$$f(x,\theta)=\frac{2x}{\theta+1}e^{-x^2/(\theta+1)}, \quad x>0$$

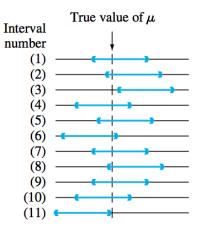

Derive the maximum-likelihood estimator for parameter  $\theta$  based on the following dataset with n = 10

 $17.85,\ 11.23,\ 14.43,\ 19.27,\ 5.59,\ 6.36,\ 9.41,\ 6.31,\ 13.78,\ 11.95$ 

## Chapters 8 and 10: Confidence intervals

Mathematical statistics

# Interpreting confidence interval

95% confidence interval: If we repeat the experiment many times, the interval contains  $\mu$  about 95% of the time

# Confidence intervals

- By target
  - Chapter 8: Confidence intervals for population means
  - Chapter 8: Prediction intervals for an additional sample
  - Chapter 10: Confidence intervals for difference between two population means
    - independent samples
    - paired samples
- By types
  - (Standard) two-sided confidence intervals
  - One-sided confidence intervals (confidence bounds)
- By distributions of the statistics
  - z-statistic
  - t-statistic

# Chapter 8: Confidence intervals

Section 8.1

- Normal distribution,  $\sigma$  is known
- Section 8.2
  - Normal distribution,  $\sigma$  is known
  - *n* > 40
- Section 8.3
  - Normal distribution,  $\sigma$  is known
  - n is small
  - ightarrow *t*-distribution

Assumptions:

- Normal distribution
- $\sigma$  is known

A 100(1 –  $\alpha$ )% confidence interval for the mean  $\mu$  of a normal population when the value of  $\sigma$  is known is given by

$$\left(\bar{x} - z_{\alpha/2} \cdot \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{\alpha/2} \cdot \frac{\sigma}{\sqrt{n}}\right)$$
(8.5)

or, equivalently, by  $\bar{x} \pm z_{\alpha/2} \cdot \sigma / \sqrt{n}$ .

If after observing  $X_1 = x_1$ ,  $X_2 = x_2$ ,...,  $X_n = x_n$  (n > 40), we compute the observed sample mean  $\bar{x}$  and sample standard deviation s. Then

$$\left(\bar{x}-z_{\alpha/2}\frac{s}{\sqrt{n}},\bar{x}+z_{\alpha/2}\frac{s}{\sqrt{n}}\right)$$

is a 95% confidence interval of  $\mu$ 

Let  $\bar{x}$  and s be the sample mean and sample standard deviation computed from the results of a random sample from a normal population with mean  $\mu$ . Then a 100(1 -  $\alpha$ )% confidence interval for  $\mu$ , the one-sample t CI, is

$$\left(\overline{x} - t_{\alpha/2, n-1} \cdot \frac{s}{\sqrt{n}}, \overline{x} + t_{\alpha/2, n-1} \cdot \frac{s}{\sqrt{n}}\right)$$
(8.15)

or, more compactly,  $\overline{x} \pm t_{\alpha/2,n-1} \cdot s/\sqrt{n}$ . An upper confidence bound for  $\mu$  is

$$\overline{x} + t_{\alpha,n-1} \cdot \frac{s}{\sqrt{n}}$$

and replacing + by – in this latter expression gives a lower confidence bound for  $\mu$ ; both have confidence level  $100(1 - \alpha)\%$ .

< 同 > < 国 > < 国 >

- We have available a random sample  $X_1, X_2, ..., X_n$  from a normal population distribution
- We wish to predict the value of X<sub>n+1</sub>, a single future observation.

A prediction interval (PI) for a single observation to be selected from a normal population distribution is

$$\overline{x} \pm t_{\alpha/2, n-1} \cdot s \sqrt{1 + \frac{1}{n}} \tag{8.16}$$

The prediction level is  $100(1 - \alpha)\%$ .

### Independent samples

- X<sub>1</sub>, X<sub>2</sub>,..., X<sub>m</sub> is a random sample from a population with mean μ<sub>1</sub> and variance σ<sub>1</sub><sup>2</sup>.
- Y<sub>1</sub>, Y<sub>2</sub>,..., Y<sub>n</sub> is a random sample from a population with mean μ<sub>2</sub> and variance σ<sub>2</sub><sup>2</sup>.
- The X and Y samples are independent of each other.

### Paired samples

- There is only one set of n individuals or experimental objects
- 2 Two observations are made on each individual or object

The two-sample *t* confidence interval for  $\mu_1 - \mu_2$  with confidence level  $100(1 - \alpha)\%$  is then

$$\overline{x} - \overline{y} \pm t_{\alpha/2,\nu} \sqrt{\frac{s_1^2}{m} + \frac{s_2^2}{n}}$$

A one-sided confidence bound can be calculated as described earlier.

• The paired t CI for  $\mu_D$  is

$$ar{d} \pm t_{lpha/2,n-1} rac{s_D}{\sqrt{n}}$$

 A one-sided confidence bound results from retaining the relevant sign and replacing t<sub>α/2,n-1</sub> by t<sub>α,n-1</sub>. If  $X_1, X_2, \ldots, X_n$  is a random sample from a distribution  $f(x, \theta)$ , then

- Find a random variable  $Y = h(X_1, X_2, ..., X_n; \theta)$  such that he probability distribution of Y does not depend on  $\theta$  or on any other unknown parameters.
- Find constants *a*, *b* such that

$$P[a < h(X_1, X_2, \ldots, X_n; \theta) < b] = 1 - \alpha$$

• Manipulate these inequality to isolate  $\theta$ 

$$P\left[\ell(X_1, X_2, \dots, X_n) < \theta < u(X_1, X_2, \dots, X_n)\right] = 1 - \alpha$$

# Examples

• For  $\mu$  and  $X_{n+1}$ 

$$rac{ar{X}-\mu}{S/\sqrt{n}}\sim t_{n-1}, \quad rac{ar{X}-X_{n+1}}{S\sqrt{1+1/n}}\sim t_{n-1}.$$

• Difference between two means [independent samples]

$$rac{(ar{X}-ar{Y})-(\mu_1-\mu_2)}{\sqrt{rac{S_1^2}{m}+rac{S_2^2}{n}}}\sim t_
u$$

• Difference between two means [paired samples]

$$T = \frac{\bar{D} - \mu_D}{S_D / \sqrt{n}} \sim t_{n-1}$$

## Chapters 9 and 10: Tests of hypotheses

Mathematical statistics

# Test of hypotheses

- By target
  - Chapter 9: population mean
  - Chapter 10: difference between two population means
    - independent samples
    - paired samples
- By the alternative hypothesis
  - >
  - <
  - ≠
- By the type of test
  - z-test
  - t-test
- By method of testing
  - Rejection region
  - p-value

In any hypothesis-testing problem, there are two contradictory hypotheses under consideration

- The null hypothesis, denoted by *H*<sub>0</sub>, is the claim that is initially assumed to be true
- The alternative hypothesis, denoted by  $H_a$ , is the assertion that is contradictory to  $H_0$ .

- $H_0$  will always be stated as an equality claim.
- If  $\theta$  denotes the parameter of interest, the null hypothesis will have the form

$$H_0: \theta = \theta_0$$

- $\theta_0$  is a specified number called the *null value*
- The alternative hypothesis will be either:

• 
$$H_a: \theta > \theta_0$$

- $H_a: \theta < \theta_0$
- $H_a: \theta \neq \theta_0$

A test procedure is specified by the following:

- A test statistic *T*: a function of the sample data on which the decision (reject *H*<sub>0</sub> or do not reject *H*<sub>0</sub>) is to be based
- A rejection region  $\mathcal{R}$ : the set of all test statistic values for which  $H_0$  will be rejected
- A type I error consists of rejecting the null hypothesis *H*<sub>0</sub> when it is true
- A type II error involves not rejecting  $H_0$  when  $H_0$  is false.

- Identify the parameter of interest
- Oetermine the null value and state the null hypothesis
- State the appropriate alternative hypothesis
- Give the formula for the test statistic
- § State the rejection region for the selected significance level  $\alpha$
- Ompute statistic value from data
- Decide whether  $H_0$  should be rejected and state this conclusion in the problem context

## Normal population with known $\sigma$

Null hypothesis:  $\mu = \mu_0$ Test statistic:

$$Z = \frac{X - \mu_0}{\sigma / \sqrt{n}}$$

. .

### **Alternative Hypothesis**

### Rejection Region for Level a Test

 $H_{a}: \mu > \mu_{0}$  $H_{a}: \mu < \mu_{0}$  $H_{a}: \mu \neq \mu_{0}$   $z \ge z_{\alpha}$  (upper-tailed test)  $z \le -z_{\alpha}$  (lower-tailed test) either  $z \ge z_{\alpha/2}$  or  $z \le -z_{\alpha/2}$  (two-tailed test)

伺 ト イヨ ト イヨト

Null hypothesis:  $\mu = \mu_0$ Test statistic:

$$Z = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$$

. .

### Alternative Hypothesis

### Rejection Region for Level a Test

 $H_{a}: \mu > \mu_{0}$  $H_{a}: \mu < \mu_{0}$  $H_{a}: \mu \neq \mu_{0}$ 

 $z \ge z_{\alpha}$  (upper-tailed test)  $z \le -z_{\alpha}$  (lower-tailed test) either  $z \ge z_{\alpha/2}$  or  $z \le -z_{\alpha/2}$  (two-tailed test)

[Does not need the normal assumption]

Null hypothesis:  $H_0$ :  $\mu = \mu_0$ Test statistic value:  $t = \frac{\overline{x} - \mu_0}{s/\sqrt{n}}$ 

### Alternative Hypothesis

#### Rejection Region for a Level $\alpha$ Test

 $\begin{array}{ll} H_{a} \colon \mu > \mu_{0} & t \geq t_{\alpha,n-1} \text{ (upper-tailed)} \\ H_{a} \colon \mu < \mu_{0} & t \leq -t_{\alpha,n-1} \text{ (lower-tailed)} \\ H_{a} \colon \mu \neq \mu_{0} & \text{either } t \geq t_{\alpha/2,n-1} \text{ or } t \leq -t_{\alpha/2,n-1} \text{ (two-tailed)} \end{array}$ 

[Require normal assumption]

#### DEFINITION The *P*-value (or observed significance level) is the smallest level of significance at which $H_0$ would be rejected when a specified test procedure is used on a given data set. Once the *P*-value has been determined, the conclusion at any particular level $\alpha$ results from comparing the *P*-value to $\alpha$ :

- 1. *P*-value  $\leq \alpha \Rightarrow$  reject  $H_0$  at level  $\alpha$ .
- **2.** *P*-value  $> \alpha \Rightarrow$  do not reject  $H_0$  at level  $\alpha$ .

DECISION	
RULE BASED	Select a significance level $\alpha$ (as before, the desired type I error probability).
ON THE	Then reject $H_0$ if $P$ -value $\leq \alpha$ ; do not reject $H_0$ if $P$ -value $> \alpha$
P-VALUE	

Remark: the smaller the P-value, the more evidence there is in the sample data against the null hypothesis and for the alternative hypothesis.

## P-values for z-tests

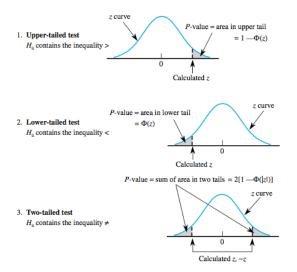

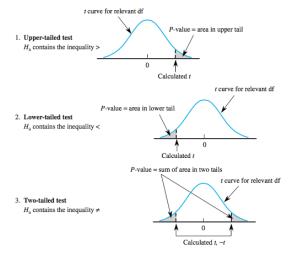

Figure 9.7 Determination of the P-value for a z test

Mathematical statistics

э

## P-values for *t*-tests

æ

# Testing by rejection region method

- Parameter of interest:  $\mu = \text{true}$  average activation temperature
- Hypotheses

$$H_0: \mu = 130$$
  
 $H_a: \mu \neq 130$ 

Test statistic:

$$z = \frac{\bar{x} - 130}{1.5/\sqrt{n}}$$

- Rejection region: either  $z \leq -z_{0.005}$  or  $z \geq z_{0.005} = 2.58$
- Substituting  $\bar{x} = 131.08$ ,  $n = 25 \rightarrow z = 2.16$ .
- Note that -2.58 < 2.16 < 2.58. We fail to reject  $H_0$  at significance level 0.01.
- The data does not give strong support to the claim that the true average differs from the design value.

## Testing by p-value

- 1. Parameter of interest:  $\mu$  = true average wafer thickness
- 2. Null hypothesis:  $H_0$ :  $\mu = 245$
- 3. Alternative hypothesis:  $H_a$ :  $\mu \neq 245$

4. Formula for test statistic value: 
$$z = \frac{\overline{x} - 245}{s/\sqrt{n}}$$

- 5. Calculation of test statistic value:  $z = \frac{246.18 245}{3.60/\sqrt{50}} = 2.32$
- 6. Determination of P-value: Because the test is two-tailed,

$$P$$
-value = 2[1 -  $\Phi(2.32)$ ] = .0204

7. Conclusion: Using a significance level of .01,  $H_0$  would not be rejected since .0204 > .01. At this significance level, there is insufficient evidence to conclude that true average thickness differs from the target value.

伺 ト イヨト イヨト

### A P-value:

- is not the probability that  $H_0$  is true
- is not the probability of rejecting  $H_0$
- is the probability, calculated assuming that  $H_0$  is true, of obtaining a test statistic value at least as contradictory to the null hypothesis as the value that actually resulted

## Testing the difference between two population means

- Setting: independent normal random samples X<sub>1</sub>, X<sub>2</sub>,..., X<sub>m</sub> and Y<sub>1</sub>, Y<sub>2</sub>,..., Y<sub>n</sub> with known values of σ<sub>1</sub> and σ<sub>2</sub>. Constant Δ<sub>0</sub>.
- Null hypothesis:

$$H_0: \mu_1 - \mu_2 = \Delta_0$$

Alternative hypothesis:

(a) 
$$H_a: \mu_1 - \mu_2 > \Delta_0$$
  
(b)  $H_a: \mu_1 - \mu_2 < \Delta_0$   
(c)  $H_a: \mu_1 - \mu_2 \neq \Delta_0$ 

• When  $\Delta = 0$ , the test (c) becomes

$$H_0: \mu_1 = \mu_2$$
$$H_a: \mu_1 \neq \mu_2$$

### Proposition

The **two-sample** *t* test for testing  $H_0$ :  $\mu_1 - \mu_2 = \Delta_0$  is as follows:

Test statistic value: 
$$t = \frac{\overline{x} - \overline{y} - \Delta_0}{\sqrt{\frac{s_1^2}{m} + \frac{s_2^2}{n}}}$$

Alternative Hypothesis Rejection Region for Approximate Level a Test

 $\begin{array}{ll} H_{a}: \ \mu_{1} - \mu_{2} > \Delta_{0} & t \geq t_{\alpha,\nu} \ (\text{upper-tailed test}) \\ H_{a}: \ \mu_{1} - \mu_{2} < \Delta_{0} & t \leq -t_{\alpha,\nu} \ (\text{lower-tailed test}) \\ H_{a}: \ \mu_{1} - \mu_{2} \neq \Delta_{0} & \text{either } t \geq t_{\alpha/2,\nu} \ \text{or } t \leq -t_{\alpha/2,\nu} \ (\text{two-tailed test}) \end{array}$ 

A P-value can be computed as described in Section 9.4 for the one-sample t test.

伺 ト イヨ ト イヨト
