Review: Logistic regression with more than 2 classes

- Suppose now the response can take any of $\{1, \ldots, K\}$ values
- We use the categorical distribution instead of the Bernoulli distribution

$$P[Y = k | X = \mathbf{x}] = p_k(\mathbf{x}), \quad \sum_{k=1}^{K} p_k(\mathbf{x}) = 1.$$

$$p_k(\mathbf{x}) = \frac{e^{w_k^T \mathbf{x}_k + b_k}}{\sum_{k=1}^{K} e^{w_k^T \mathbf{x}_k + b_k}}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Softmax activation

Feed-forward neural networks (multi-class classification)

$$p = \operatorname{softmax}(W_3^T h_2 + b_3)$$

$$h_2 = \sigma(W_2^T h_1 + b_2)$$

$$h_1 = \sigma(W_1^T x + b_1)$$
Input: x

Feed-forward neural networks

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Structure:

- Graphical representation
- Activation functions
- Loss functions
- Training:
 - Stochastic gradient descent
 - Back-propagation

Train feed-forward neural networks

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

Settings

- Data:
 (x₁, y₁), (x₂, y₂), ..., (x_n, y_n)
- Model parameters:

$$\theta = (W_1, b_1, W_2, b_2, \dots, W_L, b_L)$$

 Training: Find the best value of θ that fits the data

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Maximum-likelihood method

Average log-likelihood

$$\mathcal{L}(\theta) = \frac{1}{n} \sum_{i=1}^{n} \log P(y = y_i | \mathbf{x}_i, \theta)$$

Model parameters:

$$\theta = (W_1, b_1, W_2, b_2, \ldots, W_L, b_L)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

• Training: Maximize $\mathcal{L}(\theta)$

Cross-entropy loss (log loss)

• Cross-entropy loss = negative log-likelihood:

$$\ell(heta) = -\mathcal{L}(heta)$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

• Goal: Minimize $\ell(\theta)$

One-hot encoding

Convert a categorical value into a binary vector with exactly one "1" element, and the rest are ${\bf 0}$

Loss function for classification: cross-entropy

Code

def CrossEntropy(yHat, y): if y == 1: return -log(yHat) else: return -log(1 - yHat)

Math

In binary classification, where the number of classes M equals 2, cross-entropy can be calculated as:

 $-(y \log(p) + (1 - y) \log(1 - p))$

If M > 2 (i.e. multiclass classification), we calculate a separate loss for each class label per observation and sum the result.

$$-\sum_{c=1}^{M} y_{o,c} \log(p_{o,c})$$

Note: Here $y_{o,:}$ is the one-hot encoding of the label and $p_{o,c}$ is the predicted probability for the observation o is of class c, respectively

Stochastic gradient descent

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Gradient descent

Gradient Descent

Minimize a function by moving in the opposite direction of the gradient.

$$\theta_i := \theta_i - \rho \frac{\partial J}{\partial \theta_i}$$

Figure: Gradient Descent. Source: http://en.wikipedia.org/wiki/Gradient_descent

Gradient descent

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Stochastic gradient descent

Recall that our objective function has the form

$$\ell(\theta) = \frac{1}{n} \sum_{i=1}^{n} L(\theta, x_i, y_i)$$

- Mini-batch stochastic gradient descent
 - randomly shuffle examples in the training set, divide them into k mini-batches of data of size m
 - for each batch *l_i* (i=1, ..., k), approximate the empirical risk by

$$\hat{\ell}(\theta) = \frac{1}{m} \sum_{j \in I_i} L(\theta, x_j, y_j)$$

and update θ

$$\theta \leftarrow \theta - \rho \nabla \hat{\ell}(\theta)$$

・ロト ・ 戸 ・ ・ ヨ ・ ・ ヨ ・ ・ つ へ ()

• Repeat until an approximate minimum is obtained or a maximum numbers *M* epochs are done

Stochastic gradient descent: teminology

- Mini-batch stochastic gradient descent
 - randomly shuffle examples in the training set, divide them into *k* mini-batches of data of size *m*
 - for each batch I_i (i=1, ..., k), approximate the objective function by

$$\hat{\ell}(\theta) = \frac{1}{m} \sum_{j \in I_i} L(\theta, x_j, y_j)$$

and update θ

$$\theta \leftarrow \theta - \rho \nabla \hat{\ell}(\theta)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Repeat until an approximate minimum is obtained or a maximum numbers *M* epochs are done
- Terminology:
 - m: batch-size
 - ρ: learning rate
 - M: number of epochs

Stochastic gradient descent (SGD)

Stochastic gradient descent

- Gradient descent converges to the local minimum, and the fluctuation is small
- SGD's fluctuation is large, but enables jumping to new/better local minima

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

Escaping local minima

Automatic diffierentiation

(ロ)、(型)、(E)、(E)、 E) のQ(()

Stochastic gradient descent

 The most computationally heavy part in the training of a neural net is to compute

$$\frac{\partial \ell}{\partial \theta_{i,j}}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Numerical differentiation is not realistic, and symbolic differentiation is impossible

Automatic differentiation

Assume that

$$y = f(g(h(x)))$$

• Denote $x = u_0$, $h(u_0) = u_1$, $g(u_1) = u_2$, $f(u_2) = u_3 = y$, then

$$\frac{dy}{du_i} = \frac{dy}{du_{i+1}} \frac{du_{i+1}}{du_i}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

BACKWARD PASS (compute derivatives)

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Use chain rule to compute $\nabla \ell(\theta)$

$$\frac{\partial \ell}{\partial b_1} = \frac{\partial \ell}{\partial p}(p) \cdot \frac{\partial p}{\partial h_2}(h_2, W_3, b_3) \cdot \frac{\partial h_2}{\partial h_1}(h_1, W_1, b_1) \cdot \frac{\partial h_1}{\partial b_1}(x, W_1, b_1)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- One forward pass to evaluate h_1, h_2, p, ℓ
- One backward pass to compute $\nabla \ell(\theta)$

Feed-forward neural networks

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- Advantage: The cost to compute the partial derivatives with respect to all parameters are just twice the cost of a forward evaluations
- Drawback: The functions used to describe the network (activation functions and loss functions) needs to belong to the class of functions supported by the computational platform
