Mathematical techniques in data science

Lecture 4: Logistic Regression

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Last lecture: Nearest Neighbors

General steps to build ML models

- Get and pre-process data
- Visualize the data (optional)
- Create a model
- Train the model; i.e. call model.fit()
- Predict on test data
- Compute evaluation metrics (accuracy, mean squared error, etc.)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

• Visualize the trained model (optional)

Underfiting/Overfitting

KNN: K=1

KNN: K=100

Underfiting/Overfitting

High training error High test error

Low training error Low test error

Low training error High test error

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Underfiting/Overfitting

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

Nearest neighbors: pros and cons

Pros:

- Simple algorithm
- Easy to implement, no training required
- Can learn complex target function

Cons:

- Prediction is slow
- Don't work well with high-dimensional inputs (e.g., more than 20 features)

MNIST dataset: projected by t-SNE

Linear classification: Is it worth considering?

- Question: Linear classification: Is it worth considering?
- Answer: Yes, in combinations with proper transformation (via manifold learning) or the kernel 'trick'.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

- Despite the name "regression", is a classifier
- Only for binary classification
- Data point (**x**, y) where
 - $\mathbf{x} = (x_1, x_2, \dots, x_d)$ is a vector with d features
 - y is the label (0 or 1)
- Logistic regression models P[y = 1 | X = x]

• Then

$$P[y = 0|X = x] = 1 - P[y = 1|X = x]$$

Logistic function and logit function

Transformation between $(-\infty,\infty)$ and [0,1]

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○○○

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

• Model: Given $X = \mathbf{x}$, Y is a Bernoulli random variable with parameter $p(\mathbf{x}) = P[Y = 1|X = \mathbf{x}]$ and

$$logit(p(\mathbf{x})) = \beta_0 + \beta_1 x_1 + \ldots + \beta_d x_d$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

for some vector $\beta = (\beta_0, \beta_1, \dots, \beta_d) \in \mathbb{R}^{d+1}$.

• Goal: Find $\hat{\beta}$ that best "fits" the data

To review

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- Probability/Statistics
 - Independence
 - Bernoulli random variables
 - Maximum-likelihood (ML) estimation
- Calculus
 - Partial derivatives
 - Finding critical points of a function

Parameter estimation

- Data: $(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \dots, (\mathbf{x}_n, y_n)$, we have
- For a Bernoulli r.v. with parameter p

$$P[Y = y] = p^{y}(1 - p)^{1 - y}, \quad y \in \{0, 1\}$$

• Likelihood of the parameter (probability of the dataset):

$$L(\beta) = \prod_{i=1}^{n} p(\mathbf{x}_i, \beta)^{y_i} (1 - p(\mathbf{x}_i, \beta))^{1-y_i}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Parameter estimation: maximum likelihood

The log-likelihood can be computed as

$$\ell(\beta) = \log L(\beta)$$

= $\sum_{i=1}^{n} [y_i \log p(\mathbf{x}_i, \beta) + (1 - y_i) \log(1 - p(\mathbf{x}_i, \beta))]$

- Maximize $\ell(\beta)$ to find $\beta \rightarrow$ the maximum-likelihood method
- The term

$$-[y\log(p)+(1-y)\log(1-p)]$$

is known in the field as the log-loss, or the binary cross-entropy loss

Logistic regression: estimating the parameter

- The optimization needs to be performed by a numerical optimization method
- Penalties can be added to regularize the problem to avoid overfitting

$$\max_{\beta} \ell(\beta) - \frac{1}{C} \sum_{i} |\beta_{i}|$$

or

$$\min_{\beta} -\ell(\beta) - \frac{1}{C} \sum_{i} |\beta_i|^2$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Logistic regression with more than 2 classes

- Suppose now the response can take any of $\{1, \ldots, K\}$ values
- We use the categorical distribution instead of the Bernoulli distribution

$$P[Y = k | X = \mathbf{x}] = p_k(\mathbf{x}), \quad \sum_{k=1}^{K} p_k(\mathbf{x}) = 1.$$

Model

$$p_k(\mathbf{x}) = \frac{e^{w_k^T \mathbf{x}_k + b_k}}{\sum_{k=1}^K e^{w_k^T \mathbf{x}_k + b_k}}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Logistic regression: pros and cons

Pros:

- Simple algorithm
- Prediction is fast
- Easy to implement
- The forward map has a closed-form formula of the derivatives

$$rac{\partial \ell}{\partial eta_j}(eta) = \sum_{i=1}^n \Bigg[y_i x_{ij} - x_{ij} rac{e^{x_i^Teta}}{1 + e^{x_i^Teta}} \Bigg].$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Cons:

Linear model

How to make logistic regression better?

We want a model that

- compute the derivatives (of the objective function, with respect to the parameters) easily
- can capture complex relationships

This is difficult because complex models often have high numbers of parameters and don't have closed-form derivatives, and computations of

$$rac{\partial \ell}{\partial eta_i}(x) pprox rac{\ell(x+\epsilon_i)-\ell(x)}{\epsilon_i}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

are large (and unstable)

Next lecture

- Automatic differentiation and back-propagation
- Ideas:
 - Organizing information using graphs (networks)
 - Chain rule

$$(f \circ g)'(x) = f'(g(x))g'(x)$$
